PROFESSIONAL SUMMARY

DevOps and Cloud Engineer who designs, builds, and operates Kubernetes infrastructure on AWS end-to-end. Sole engineer on TaskFlow, a cloud-native platform on EKS with GitOps deployments and zero static credentials, and infrastructure team lead on a 23-engineer fintech build delivering 45 Terraform-managed AWS resources. Detects and resolves incidents with MTTR under 17 minutes. Open to remote opportunities worldwide.

CORE SKILLS

Kubernetes and Infrastructure as Code: EKS, Docker, Helm, HPA, PodDisruptionBudgets, Network Policies, AWS Load Balancer Controller, Terraform with S3 remote state and modular architecture

CI/CD and GitOps: GitHub Actions, 6-stage multi-environment pipelines, OIDC authentication, ArgoCD sync, prune and self-heal, ArgoCD Image Updater

AWS: EKS, EC2, ECS, RDS, ElastiCache, VPC, IAM, ALB, ECR, S3, SSM, ACM, Route53, CloudWatch

Security: IRSA, External Secrets Operator, SSM Parameter Store and Session Manager, Trivy scanning, CVE triage, multi-tenant isolation with automated tests, non-root containers, TLS

Observability and Incident Response: Datadog, Prometheus, Grafana, Fluent Bit, CloudWatch Logs, alert tuning, synthetics, root cause analysis, postmortems, runbooks, Bash remediation

Linux and Networking: Ubuntu administration, systemd, Nginx, cron, Bash, VPC design, DNS, security groups, pod CIDR routing

WORK EXPERIENCE

Co-Trainer and DevOps Engineer | Digital Witch Support Community | Abuja, Nigeria (Remote, Part-Time) | 01/2025 - Present

- Provisioned AWS infrastructure with Terraform across development, staging, and production for the community's training platform, cutting environment setup from multi-day manual work to a version-controlled deployment any engineer can run from zero.
- Automated delivery with a 6-stage GitHub Actions pipeline using OIDC authentication across frontend and backend microservices, removing every static credential from the process.
- Built a Datadog observability pipeline across 2 EC2 servers and tuned alert thresholds to cut false positives while still catching real traffic drops within 5 minutes, then validated alert-to-recovery end-to-end through controlled incident drills.

DevOps Engineer and Dev Team Lead | ScaleUpBuild - HelloAgain (Volunteer, Remote) | 07/2026 - Present

- Lead the dev team and own infrastructure design for an AI-powered WhatsApp commerce platform: AWS via Terraform, multi-environment Kubernetes with ArgoCD GitOps, GitHub Actions CI/CD, and always-on webhook infrastructure for the WhatsApp Business API.
- Drove architecture decisions to resolution before build, surfacing real-time layer trade-offs, multi-tenant isolation, and data residency to leadership, preventing rework from premature provisioning.

Infrastructure Team Lead | Fintech Banking Platform, Digital Witch Pod 13 (Team Project) | 04/2026 - 05/2026

- Led the 7-person infrastructure team on a 3-tier banking platform built by 23 engineers across infrastructure, application, and GitOps teams, provisioning 45 AWS resources including a multi-AZ VPC and an auto-scaling EKS cluster through Terraform, with no resources created in the console.
- Recovered the platform after the Terraform state bucket was deleted mid-project, leaving every live resource untracked including a running EKS cluster; restored state and enabled versioning so the team could no longer lose it.
- Automated every release through ArgoCD with Nginx Ingress and Cert Manager handling TLS renewal, giving a full audit trail and one-command rollback, and kept infrastructure off the critical path for the backend and delivery teams.

Customer Service and Operations | Various Roles | Nigeria | 2017 - 2024

- 8 years resolving customer issues end to end across hospitality, retail and consumer electronics, building the communication, escalation and documentation discipline now applied to infrastructure incident response.

TECHNICAL PROJECTS

TaskFlow - Cloud-Native Kubernetes Platform on AWS EKS | thetaskflowapp.online | github.com/elizabeth-ikechukwu/scalable-task-platform

- Designed, built, and ran a microservices platform on AWS EKS, owning every orchestration, security, CI/CD, and observability decision. The cluster is now torn down for cost; the live demo serves the same images from a single EC2 instance, and the full platform is reproducible with one terraform apply.
- Provisioned multi-AZ infrastructure across 8 Terraform modules with S3 remote state: VPC, EKS managed node groups, RDS PostgreSQL in private subnets, ECR, 6 IRSA roles, ACM and Route53, with the AWS Load Balancer Controller handling HTTPS termination and path-based routing. No infrastructure change made outside the pipeline.
- Eliminated static credentials across the stack: each pod authenticates to AWS with a short-lived IRSA identity, External Secrets Operator syncs from SSM hourly, SSH is replaced by SSM Session Manager, and the pipeline signs in through OIDC.
- Blocked vulnerable images from reaching the registry with Trivy failing the build on CRITICAL and HIGH CVEs, then ArgoCD with sync, prune, and self-heal for zero drift, HPA scaling 2 to 5 replicas, PodDisruptionBudgets for zero-downtime maintenance, and Prometheus, Grafana, and Fluent Bit from day one.

PulseOps - Multi-Tenant Incident Management Platform, Live pulseops-app.online | github.com/elizabeth-ikechukwu/pulseops | github.com/elizabeth-ikechukwu/pulseops-infra

- Designed and shipped it from database schema to AWS infrastructure: a VPC across 2 availability zones, RDS PostgreSQL and ElastiCache Redis in private subnets, ECS on EC2, and a pipeline that tags every image with its commit SHA and rolls out a new task revision on merge.
- Removed the hour teams lose reconstructing an incident: every resolved incident auto-generates a blameless postmortem pre-filled with the real timeline and response times.
- Proved tenant isolation instead of assuming it: a test that fetches another organization's incident by exact record ID fails by design, 1 of 29 tests run on every push across auth, tenant boundaries and the incident lifecycle.
- Caught a live-infrastructure bug before it caused a silent, unalerted rollback: traced a conflict between Terraform and the pipeline over which app version was authoritative, then split ownership so each system controls only what it should.

Monitoring and Incident Response on AWS EC2 | github.com/elizabeth-ikechukwu/technical-support-portfolio

- Ran 4 production-style incidents on a live EC2 server to prove the alerting worked: Nginx down, CPU at 95%, disk past 80%, and an HTTP 502 caught by a Datadog synthetic check. Detection took 1 to 11 minutes, and every incident was closed within its SLA.
- Found the disk alert was watching the wrong disk, so it would have stayed silent through the exact failure it was written for, and corrected it. Automated the 2 most common failures with cron-scheduled Bash scripts, each with a report and runbook.

Distributed Inference Platform on AWS | github.com/elizabeth-ikechukwu/alchemyst-devops-assignment

- Ran a language model across 3 EC2 instances with 1 public entry point, workers in a private subnet reaching out through NAT only, connected over WebSocket RPC, sized per workload and defined entirely in Terraform.

EDUCATION AND CERTIFICATIONS

CKA (Certified Kubernetes Administrator) | In Progress

DevOps & Cloud Security Certification | Digital Witch Support Community | 06/2026

BSc Cybersecurity | Miva Open University, Abuja, Nigeria

Technical Support Fundamentals | Google / Coursera | 11/2025
